

Money Attitudes & Personality Analysis

Quantitative Research Project | SPSS | Survey Data

1. Research question

The project investigates relationships between personality characteristics and attitudes toward money during a period of economic and political uncertainty.

2. Sample and measures

The study includes 78 respondents aged 16–70. Measures include a 47-item Money Beliefs & Behaviour questionnaire and additional measures of uncertainty tolerance, life satisfaction, financial anxiety and personal values.

3. Statistical methods

Quantitative analysis was conducted in SPSS. Descriptive statistics were used to summarise the sample and questionnaire responses. Spearman rank correlations were used to identify relationships between variables, and factor analysis was used to investigate underlying patterns across money-related measures.

4. Key findings

The reported results identify statistically significant relationships between age and material status and employment involvement, as well as relationships between age and several money-related attitudes. Older respondents showed lower financial anxiety in the reported analysis. The value-ranking analysis placed family, work and health among the highest-ranked values, with money ranked fifth.

5. Analyst skills demonstrated

This project demonstrates survey-data preparation and interpretation, descriptive statistics, non-parametric correlation, multivariate dimension reduction through factor analysis, and communication of quantitative findings in a research setting.

6. Portfolio note

This is presented as an academic quantitative research project. The public repository does not include the original respondent-level dataset or claim access to unavailable SPSS syntax.
